I get the point

- silent errors are tricky
- I've just checked and it looks for Zero write bytes before writing
- not a problem nowadays – but lethal under MSDOS

>But once a file (stream) is satisfactorily opened I wonder what the
>base cause would be of any errors which could cause a write failure
>(particularly on a single PC).

Unrecoverable for sure

One thing .. I once got burnt by Write(S[1], Length(S))
– when S was zero length

- the upside was it got me to turn on range checking
 - permanently
- <G>

.
