Hi

I have an app that connects to a database every 15 seconds to gather data then disconnects. The system is designed to run on a dial-up connection, but has been mostly developed on a broadband connection.

It has only come to light today that when running on a 56k modem every time it connects to the database the app slows/freezes and will not take any keyboard input until it is finished. I have been told that this may be to do with threads/processor time. I am using a componet called MySQLDAC from MicroLab, I have contacted them but they can't send me any example code for about 2 weeks, trouble I need it now (it's that always the way)

Does any body know how to create a threads so that database connection is on one thread and the main app runs OK

Best to warn you I'm not 100% sure on what threats are or how they work, I have had a look round the net for some help but can't seem to find any

Brian
