Ahh I see. I was thinking of something along these lines, but I'm not sure how to actually display the form modally at a certain position on the screen (when you have worked out the position)? ShowModal only returns an integer and doesn't allow you to specify anything.

One way which would work i suppose is setting the left and top properties OnShow of the second form, so this would be after calling showmodal rather than before as you specified, correct?

I'm showing a second form modally through a button on my main form. I have the position property of the second form set as poMainFormCenter – but if I have my main form at the edge of the screen, the second form is shown half hidden (the rest of it is off the screen). I'm thinking this would be complicated to solve – I.E: to detect whether the form is shown off the left of the screen or not, and display it accordingly..?

At least in a single screen configuration, you should be able to figure this out yourself by checking screen.width, screen.height and form1.width, form1.height before calling the showmodal.
