My VB6 application needs customer data like name/address/place_of_birth etc.

This customer data is available in Excel sheets.

I think the easiest way is to use some database which is controlled by VB6. But thats all I know.

I recall hearing somewhere that you can actually use an ODBC driver to access an Excel document. Of course, that's a gross hack, but it is Microsoft software, so...

Anyway, if you can access ODBC databases from VB6, I guess you could do it that way.

Of course, a better solution might be to not store the data in an Excel spreadsheet in the first place, if it needs to be accessed programmatically.
