Ok so there is a website that has two input boxes inside a POST form that uses the action="rcon.php"

here is the code for the form

```
<form method=POST action="/rcon.php">
<input size=25 type=text class="sm" name="addr">
<input size=20 type=text class="sm" name="rcon">
<input class="coolbuttonblue" type=submit value="Submit">
<input class="coolbutton" type=checkbox name="announceflag" value="1"
checked>
```

What I want to do is to be able to execute this script without having to fill out the form every time. My ideal thought was to make a shortcut to the URL <http://whateversite.com/rcon.php?addr=someaddress&rcon=somercon&announceflag=1> and that way everytime i click the shortcut, it executes the script, and passes it static data that I put in the shortcut, therefor I don't have to fill out a form every time and click submit.

This is not my website I am dealing with, it is a public site that uses a form that has the code above. So why can't I just pass the data through the address bar? Is there some security in place that might prevent url passing of variables?

If I can't do that, would writing a script that uses sockets be able to accomplish this somehow? Or is it somehow not possible without using their html form
