Is there any way to tell PHP predefined variables (\$GLOBALS, \$argv, \$argc, \$\_GET, \$\_POST&) from \*global\* user-defined variables? Neither \$GLOBALS nor get\_defined\_vars() put user data apart.

I m writing a class to generate PHP definition files for syntax highlighting with two features:

1. It takes data from current install (e.g., you get function names from loaded extensions).
2. You can choose whether to include user data or not.

It s been very easy with functions and constants but I can t figure out how to deal with variables, rather than hard-coding the names of predefined vars... I ve kind of automated this hard-coding but it still smells of lame workaround.
