Hi,

I have a small application made in flash, that uses a set of PHP scripts to pull data from a database. I've added sessions to this scripts so they would only return the data if a proper session has been initialized, the flash movie is hosted in a sessioned php as well so you can only see it if a session has been initialized.

All of it works well, the flash movie calls the scripts and the scripts return the data if and only if a session has been started. all of this was tested on Apache 2.2.2 and PHP 5.1.6 and works as expected. however, moving the whole thing to another server running Apache 2.2.6 with PHP 5.2.4 does not work, the flash movie calls the scripts, but it seems to be calling them outside the session set in PHP, thus the scripts return and invalid session message, if we call the scripts directly once the session has been initialized they return the correct data.

So, the question is, is the above working because we are relaying on some bug in the previous versions of apache+php or are we missing some setting in the new versions ? We have tried to find a relevant setting making a difference but so far we are not able to do so.

Thank you very much for your help.

Regards.
