Hallo,

i m using perl for parsing the queries in xml files, so i have written two seperate progarms one is "local.pl" and the other one is "inter.pl". The fisrt program gets the list of proteins from first xml file gives as an output, and now i want to use this output of loca.pl as the input for inter.pl, it checks whether these datas exist in second xml datafile.

i have already tried it out by combining the both codes and created an object of loca.pl in inter.pl. but it didnt work. So, may be i have done some mistakes.

Could someone please tell me how to use output of one class into another class.

Thanks in advance

gautam
