

Problem with Large Query Returns from MS-SQL

Hello,

I am writing an application that is using DBI to access a MS SQL database hosted on a remote server. I think I am having trouble with larger result sets.

For example:

If I do

```
$stmt = "SELECT * FROM tableA";
```

Where where tableA is around 10 rows, then my test script returns all of the rows in the table and prints them out to the user on the browser.

However, if I do:

```
$stmt = "SELECT * FROM tableB";
```

Where tableB is around 6000 rows, the script does not produce any results and continues with the rest of the script with an empty result set. Even if I put conditions on the query for the large table that would return only 2 or 3 rows, the result set is not returned.

Does DBI have some kind of default timeout setting that breaks off after waiting for a query result? If so, can I alter it somewhere?

I should also mention that all of the queries I am trying in the script work fine when I directly call them on the database.

Thank you,

Jordan
