I understand
package require tcom
set UserInfo [::tcom::ref getobject "WinNT://\$Domain/\$User"]
\$UserInfo name
\$UserInfo fullname
\$UserInfo Accountdisabled
All those operate as expected.

What is the syntax to get other properties of the user. None of the tricks I use – looking in AD or ldap explorer seem to yield anything. I am looking specifically for the email account = mail in LDAP; E-mail in AD. Tried all the case permutations.

All respond with
object does not implement method or property

```
::tcom::info interface $UserInfo  
returns  
cannot get type information
```

I know I am missing something obvious – I have been able to operate Excel worksheets and parse out existing properties.

Other ways to get same sort of info?

.
